AI BIASES VS HUMAN BIASES

PABLO WINANT, ESCP BUSINESS SCHOOL

A SMALL QUESTION

- Are you ready to be driven by an AI-driven car, 5 years from now?
- Info about car accidents (today)
  - AI: 9 crashes per million mile
  - human: 4 crashes per million mile
  - but almost not majo injury in AI driven cars
- AIs are easy to fool
  - incorrect reading of traffic signs with small modifications
  - see nature

AIS WILL TAKE MORE AND MORE DECISIONS

- AIs will take more and more decisions
  - decide what you'll watch on Netflix
  - drive your car
  - select the recruits you will hire
  - decide whether you should be receiving treatment from the nearby hospital
  - invest your personal finances
  - decide optimal monetary policy of the central bank
- But there will always be a human overseeing these AI decisions?
- ...right?

WHAT IS A DECISION

- Several seemingly different cases:
  - recommendation
  - decision with immediate consequences
  - a part of a decision process
- These cases are not so clearly separable
- Precise agency is not important here
- We'll call of these "decisions"
  - (alternatives: "predictions"/"choices"/...)

Cassie Kozyrkov, chief decision scientist from Google:

We define the word “decision” to mean any selection between options by any entity

DECISION INTELLIGENCE

- Who studies AI decisions?
- A new emerging field: "Decision Intelligence"
- Defines "decisions" as
  - a choice of an "output" from a set of "input"
  - choice is irreversible
- Relates data-science with different fields

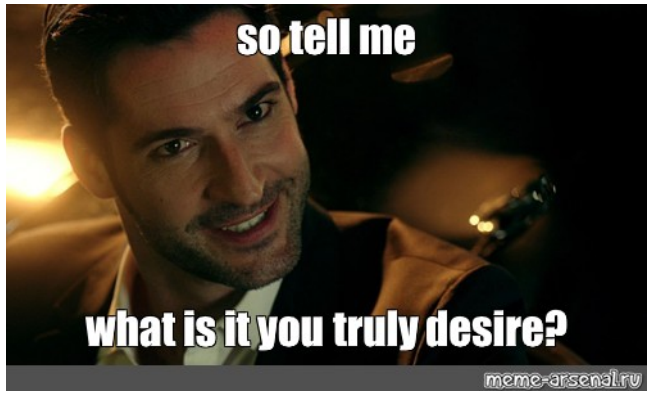
Example of questions: (from Cassie Kozyrkov, chief decision scientist from Google)

The decision sciences concern themselves with questions like:

- “How should you set up decision criteria and design your metrics?” (All)
- “Is your chosen metric incentive-compatible?” (Economics)
- “What quality should you make this decision at and how much should you pay for perfect information?” (Decision analysis)
- “How do emotions, heuristics, and biases play into decision-making?” (Psychology)
- “How do biological factors like cortisol levels affect decision-making?” (Neuroeconomics)
- “How does changing the presentation of information influence choice behavior?” (Behavioral Economics)
- “How do you optimize your outcomes when making decisions in a group context?” (Experimental Game Theory)
- “How do you balance numerous constraints and multistage objectives in designing the decision context?” (Design)
- “Who will experience the consequences of the decision and how will various groups perceive that experience?” (UX Research)
- “Is the decision objective ethical?” (Philosophy)

THE SPECIFICITIES OF AN ECONOMIC APPROACH

- Consider different ways to analyse AI behaviour from an economic perspective (*people's decisions*)
  - deviations from rationality
  - specification of a precise objective



THREE KINDS OF BIAS

- predictive bias
  - ... we know what want but are doing it wrong
- preference bias
  - ...we're wrong about the ultimate objective
- behavioural bias (next week)
  - ...we're doing it wrong

PREDICTION BIAS

DEFINITION OF STATISTICAL BIAS

Prediction Bias: systematic error made by an algorithm producing a prediction

- Here, *systematic* must be understood as *in average* or *in expectation*

SOURCES OF PREDICTION BIASES

- Problems with the data (*data-driven*)
  - **selection bias**
  - **attrition bias**
  - ...
- Problems with the model (*algorithmic bias*)
  - **ommitted variable bias**
  - ...
- Other sources (essentially *human bias*)
  - funding bias
  - social prejudice
  - human limitation
  - ...

IMAGE LABELLING

An AI or you must choose labels to best describe this image:

AN EXAMPLE OF A SELECTION BIAS

Obviously, the way the AI (or you) makes category, depends on the dataset it has been exposed to.

- Experience/learning produces a **prototype** of a watermelon (i.e. an object representative of its class)
- When a **prototype** is not representative of some data it becomes a **stereotype**
  - it creates **bias**

HOW DO WE MEASURE IT ?

- Sometimes bias is easy to measure with
  - precise criterium (e.g. no discrimination)
  - precise measure (e.g obvious distribution discrepancies)
- But in general it requires:
  - an experiment
  - some econometric work
- Often, biases are easier to assert for AIs than humans
  - their training occurs in a controlled environment

DO YOU WANT TO BE TREATED BY AN AI?

Nature, 25/01/2017: Dermatologist-level classification of skin cancer with deep neural networks

- analyze skin images to recognize malignant melanoma
- as good as human dermatologists
- more cost-effective (can work on a smartphone)

DO YOU (REALLY) WANT TO BE TREATED BY AN AI?

The Lancet, 2022: *Characteristics of publicly available skin cancer image datasets: a systematic review*

- They review 21 open access databases, with skin lesion images
  - 106 950 images
  - `Of the two datasets containing data on ethnicity (1585 images in total), 45, 47 no images were from individuals with an African, Afro-Caribbean, or South Asian background`
  - `Coupled with the geographical origins of datasets, there was massive under-representation of skin lesion images from darker skinned populations.`
- Conclusion?

OR DO YOU PREFER TO BE TREATED BY A HU(MAN) ? (1)

Health Services As Credence Goods: A Field Experiment
(Gootschalk, Mimra, Weibel)

- The same "test patient" was sent to 180 dentists who offered treatment recommendation and cost estimate.
- Test patient did not need treatment (caries lesions limited to enamel).
- 28% of practitioners made a wrong treatment recommendation! 😲
- What were the determinants of the bias?
  - Social Economic Status (-)
  - Lower Waiting Time (+)

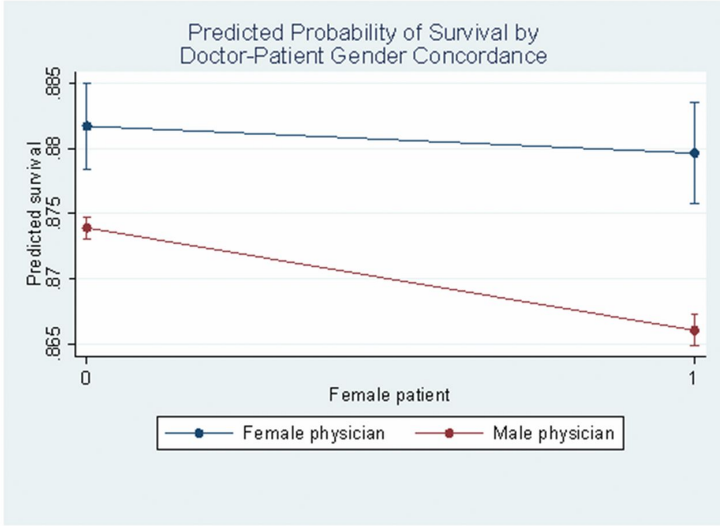
OR DO YOU PREFER TO BE TREATED BY A HU(MAN) ? (2)

Perceived Risk of Heart Attack: A Function of Gender?
2004, (Leanne L Lefler)

- mortality rate for women in the year immediately after suffering a heart attack was 38%, compared to 25% for men
  - woman delay assistance seeking (it's a men problem)?

Patient–physician gender concordance and increased mortality among female heart attack patients
(Greenwood, Carnahan, Huang)

- higher probability of survival when same-sex doctor
- driven by treatment from male doctors (the majority of cardiologists)



MARKET BIAS

- Job Market
  - *Job discrimination*: the decision to hire someone at a given salary should not depend on his/her gender, appearance, social origin, age, ethnicity, ...
  - *Wage gap*: also the wage gap between people with the same overall productivity should be zero, no matter their gender, appearance, ...
- Big problems:
  - how do you measure "same overall productivity"?
    - wrong measurement leads to **ommitted variable bias**
  - how do you find two people with different characteristics and exactly same productivity?
    - in general many characteristics are linked with productivity (for instance, name is correlated with IQ)

A NOT SO-FICTIVE EXAMPLE OF A FAILED ANTI-DISCRIMINATION POLICY

Bob from Texas

FAMOUS EXAMPLE: AMAZON

Reuters 11/10/2018: Amazon scraps secret AI recruiting tool that showed bias against women

- What happened?
  - Amazon started to train (use?) internally a ML algo to preselect CVs and counteract human biases
  - Algorithm started to discriminate against woman
  - Sentences containing strings like "women's" were discriminated against (like "champion of women's chess cup")
  - Program was dismantled

ANOTHER HUMAN BIAS

- PNAS 2017, *Extraneous factors in judicial decisions*, Danziger, Levav and Avnaim-Pesso
  - analyse parole decisions by boards presided by jewish isreali judges
  - probability of "parole" falls between the two snack breaks! 😱
  - find a strong "hungry judge effect"

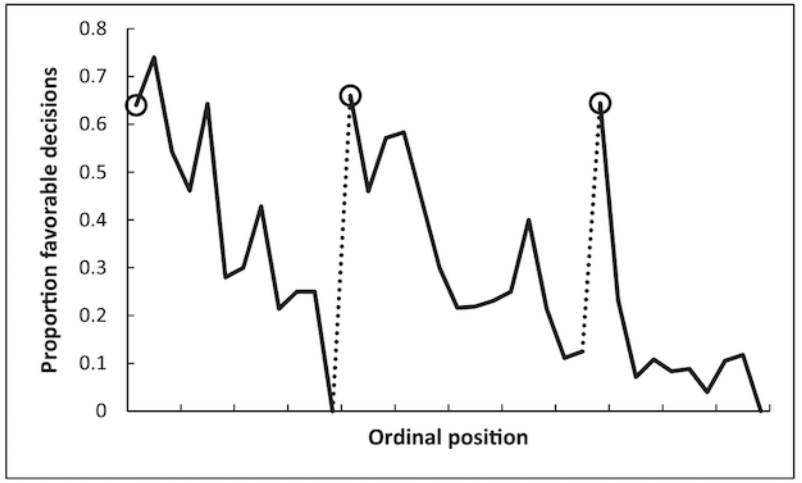


Fig. 1. Proportion of rulings in favor of the prisoners by ordinal position. Circled points indicate the first decision in each of the three decision sessions; tick marks on *x* axis denote every third case; dotted line denotes food break. Because unequal session lengths resulted in a low number of cases for some of the later ordinal positions, the graph is based on the first 95% of the data from each session.

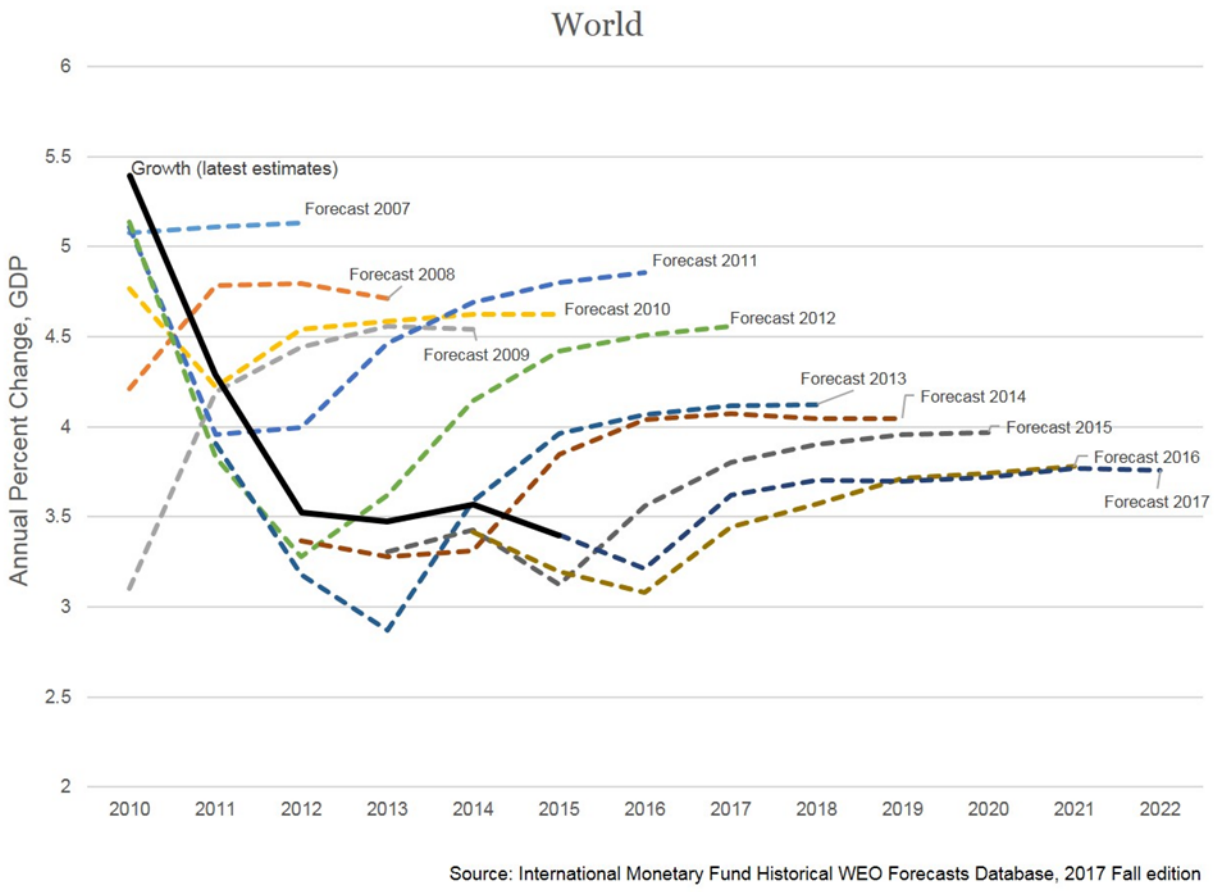
CONCLUSIONS

- AI and humans *both* suffer from **selection bias**
- AI can reproduce human biases
  - in the way algorithm is designed
  - if it immitates humans or if its objective incorporates human bias, conscious or not
- AI's don't have all human biases
  - no hungry judge effect
  - no funding cost (or do they?)

ANOTHER EXAMPLE: WEO FORECAST

Here is the history of IMF forecasts (form WEO 2017)



Is it biased?

PREFERENCE MISSPECIFICATION

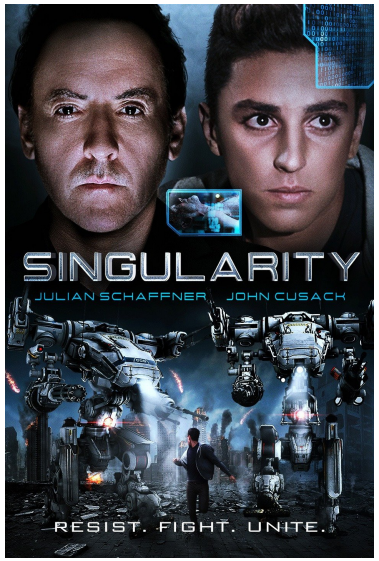
WHAT IS THE RIGHT WAY TO DESCRIBE ECONOMIC BEHAVIOUR?

- In economics, we derive agent's behaviour from their ultimate objective
  - maximize profits
  - maximize consumption, leisure
  - something else
- This is very close to the implementation of AI now:
  - ML: miniminize empirical risk (sum of square residuals), maximize the fit
  - AI: robots are explicitely told what to do (not how)
- Biases should be precisely defined w.r.t. a well specified goal

EXAMPLE: BREXIT

- Was the collective decision of leaving the UK biased, based on available evidence?
- Here, the objective might not be well specified. There are unsaid, unconscious, objectives

EXAMPLES: AI OBJECTIVE MISSPECIFICATION

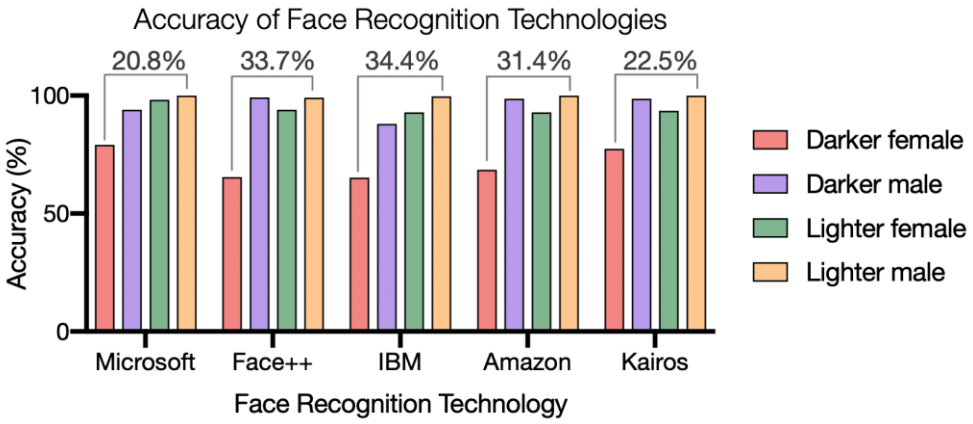


- AI with the wrong objective is evil
- Explored a lot in science-fiction
  - Asimov's law of robotics
  - the smiling man, ...
- Many (all?) "mistakes" from AI come from **preference misspecification**

EVOLUTIONARY BIAS

- It is sometimes optimal to keep a biased decision process in certain situations
- When taking bias decisions provides a survival advantage, it is called an **evolutionary bias**
  - treat unknown species as "hostile"
- Rationals
  - Limit processing cost
  - Provide informational value, i.e. help to learn faster
  - ...

AN EXAMPLE OF "TRIMMING"



- AI algorithm have become very good at recognizing and distinguishing faces...
  - ... mostly white men
  - selection bias again
- Adults have the same biases: they distinguish better faces from their own reference group
- Strikingly 6 month old babies don't: they recognize all faces (Netflix: "babies")
- The unlearning is called trimming (to save brain resources???)
- Same happens with language: initially babies can distinguish all sounds in all languages

AN EXAMPLE OF LEARNING EXTERNALITY

- Why do newer movies have better ratings than older ones on movie databases (like Allocine)
- And why are website not doing anything about it?
- New movies are intentionnaly overrated
  - to push consumers towards "exploring"
  - to produce more information
  - and improve the rating of new movies
- It can be interpreted as a learning externality

ESCP BUSINESS SCHOOL

PREFERENCES VS UTILITY

- Another issue is that *humans are not one-dimensional maximizers*
- Theories of **preferences** are larger than utility maximization
  - Among choices $\mathcal{X}$, we say that x is preferred to y if $x \geq y$
- Preferences can be more general than utility maximization
  - ideally transitive if $x \geq y$ and $y \geq z$ then $x \geq z$
  - but there isn't necessarily a total order (complete ranking) $x_1 \geq \cdots \geq x_n$
  - even if there is there is no notion about "how much" x is preferred to y
- Generalized Preferences arise naturally from
  - real-world individuals
  - multi-objective agents
  - collective choices (cf Arrow Theorem)

MULTI-OBJECTIVES

- Ideal AIs should be multi-objectives:
  - have sensible default for out of sample situations
  - produce more intelligent behaviour
  - mitigate wrong objectives given by humans
- The problem is when AIs are trained to follow multiple objectives (which they need if they need a notion of context) their bias become harder to measure/explain

EXAMPLE: PARCOURSUP, A MULTI-OBJECTIVE RANKING ALGORITHM

- parcoursup match universities wishes and students wishes
  - it aggregate individual's preferences
  - while respecting current laws
- it is a variant of a stable marriage problem
- how do you formulate the optimum?
  - impossible to satisfy everybody
- implementation details makes random decisions
  - in order to avoid bias!
  - and satisfy local regulations
- has created a lot of discontentment

CONCLUSIONS

- The concept of predictive bias is contingent to the right, scalar (i.e. a number), objective specification
- Formulating the wrong the objective leads to a prediction bias
- Objectives are inherently hard to formulate exhaustively
- The presence of several objectives complicates the pictures
  - for humans
  - and AIs

BEHAVIOURAL BIASES

- ... Next time:
  - how do we know when humans act non-rationally?
  - Can we then establish some patterns in their behaviours?

FINAL WORD

It's good to follow your own bias as long as it is climbing it.

Andre Gide
